

SharePoint (MOSS 2007) Case Study

Software Development Project Monitoring System for a Telecom major

We are building a software development project monitoring system for use by executives at client's premises which provides a bird's eye view of current status and progress against targets of numerous software projects currently in development for the client.

Core Features

- A business dashboard displaying milestones, KPIs and high-level indicators on all project elements, with calendar view, that allows drill-down to appropriate details like requirements documents, technical and UI specifications, and project related minutes.
- A dashboard for status information about critical services
- An interface allowing individual team members to contribute towards project status, tasks, milestones and risk identification
- An interface allowing executives to deliver feedback on performance versus goals and timelines
- Discussion forums

This system combines MOSS 2007 (including custom web parts, custom lists, custom workflows, document collaboration, standard site templates, calendars, email integration, and task coordination) with SQL Server 2005, .Net 2.0, and Excel Services.
